

AMENDMENTS TO THE CLAIMS

Claims 1-103 (Canceled)

Claims 104-127. (Canceled)

128. (Currently Amended) A device for providing additional stabilization to tissue already in contact with a primary stabilization member, said device comprising:

a single, substantially rigid, tissue contact member formed in a unitary, continuous loop and adapted to be placed on the tissue in an area bounded by primary tissue contact members; and

a connecting member extending from said at least one tissue contact member and adapted to be hand held or fixed to a relatively immovable object.

129. (Original) The device of claim 128, wherein said at least one tissue contact member comprises a base member having a central opening therethrough, said central opening adapted to allow access to a target site on the tissue.

130. (Original) The device of claim 129, wherein said base member is substantially oval-shaped.

131. (Original) The device of claim 130, wherein said oval-shaped member cants upwardly around an outer perimeter thereof in the shape of a cowboy hat.

132. (Original) The device of claim 129, wherein said base member has a substantially hollow interior adapted to develop a negative pressure therein.

133. (Original) The device of claim 132, wherein said connecting member fluidly connects with said substantially hollow interior and is adapted to be connected to a source of negative pressure.

134. (Original) The device of claim 132, wherein said base member further comprises openings through a bottom surface thereof, said openings being fluidly connected with said substantially hollow interior and adapted to apply a negative pressure to the tissue.

135. (Original) The device of claim 134, wherein said base member further comprises openings through an upper surface thereof, said openings through said upper surface being fluidly connected with a lumen that is connectable with a source of pressure that is independent of a pressure in said substantially hollow interior of said base member.

136. (Original) The device of claim 135, wherein said lumen runs inside of said connecting member.

137. (Original) The device of claim 135 further comprising a manifold mounted inside said base member and fluidly connecting said lumen with said openings through said upper surface.

Claims 138-144. (Canceled)

145. (Previously Presented) A device for providing additional stabilization to tissue already in contact with a primary stabilization member, said device comprising:

at least one tissue contact member adapted to be placed on the tissue in an area bounded by primary tissue contact members, wherein said at least one tissue contact member comprises a substantially oval-shaped base member having a central opening therethrough, said central opening adapted to allow access to a target site on the tissue, and wherein said substantially oval-shaped base member cants upwardly around an outer perimeter thereof in the shape of a cowboy hat; and

a connecting member extending from said at least one tissue contact member and adapted to be hand held or fixed to a relatively immovable object.

146. (Previously Presented) A device for providing additional stabilization to tissue already in contact with a primary stabilization member, said device comprising:

at least one tissue contact member adapted to be placed on the tissue in an area bounded by primary tissue contact members, wherein said at least one tissue contact member comprises a base member having a central opening therethrough, said central opening adapted to allow access to a target site on the tissue, said base member further having a substantially hollow interior adapted to develop a negative pressure therein, wherein said base member further comprises openings through a bottom surface thereof, said openings being fluidly connected with said substantially hollow interior and

adapted to apply a negative pressure to the tissue, and openings through an upper surface thereof, said openings through said upper surface being fluidly connected with a lumen that is connectable with a source of pressure that is independent of a pressure in said substantially hollow interior of said base member; and

a connecting member extending from said at least one tissue contact member and adapted to be hand held or fixed to a relatively immovable object.

147. (Previously Presented) A device for providing additional stabilization to tissue already in contact with a primary stabilization member, said device comprising:

at least one tissue contact member adapted to be placed on the tissue in an area bounded by primary tissue contact members, said at least one tissue contact member comprising a base member having a central opening therethrough, said central opening adapted to allow access to a target site on the tissue, said base member further having an outer perimeter portion that cants upwardly from a lower surface of said base member located interiorly of said outer perimeter portion, so that said lower surface located interiorly contacts the tissue while said outer perimeter portion contacts the primary stabilization member; and

a connecting member extending from said at least one tissue contact member and adapted to be hand held or fixed to a relatively immovable object.

148. (New) A device for providing additional stabilization to tissue already in contact with a primary stabilization member, said device comprising:

a single, substantially rigid, tissue contact member formed in a continuous loop and adapted to be placed on the tissue in an area bounded by primary tissue contact members; and

a connecting member integrally formed with and extending from said at least one tissue contact member and adapted to be hand held or fixed to a relatively immovable object.

149. (New) A device for providing additional stabilization to tissue already in contact with a primary stabilization member, said device comprising:

a single, substantially rigid, tissue contact member formed in a continuous loop and adapted to be placed on the tissue in an area bounded by primary tissue contact members, wherein said at least one tissue contact member comprises a base member having a central opening therethrough, said central opening adapted to allow access to a target site on the tissue, and wherein said base member is

substantially oval-shaped and cants upwardly around an outer perimeter thereof in the shape of a cowboy hat; and

a connecting member extending from said at least one tissue contact member and adapted to be hand held or fixed to a relatively immovable object.
